# CSE216 Foundations of Computer Science

Instructor: Zhoulai Fu

**State University of New York, Korea** 

- What we have learned about ocaml:
  - primitive types, functions including comparison operators, let definitions, let in expressions, if expressions, functions, types of functions, user-defined types including sum types, product types and record types, pairs, tuples, unit
- Today: Lists

## Some review questions

#### Question #1

#### A **tuple** contains...

- A. A fixed number of components all of which must have the same type
- B. Exactly two components which may have different types
- C. A fixed number of components each of which may have a different type
- D. Exactly two components which must have the same type
- E. I forgot to study tuples

#### Question #2

To access the first component of a pair, I can use...

- A. The fst projection function
- B. Pattern matching with a **let** expression
- C. The unit expression
- D. A and B
- E. A and C

#### Question #3

B.int\*int

C.string\*int

D.int\*string

E.string\*(string\*int)

```
What is the type of this expression?
let (x,y) = snd("zar",("doz",42))
in (42,y)
A. {x:string; y:int}
```

What is the type of (1,2,3)?

 What is the type of sum\_triple in sum\_triple ((x: int), (y: int), (z: int)): int = x+y+z

 Write a function of type int->int->int->int that returns the sum of three ints

### Lists

### Lists

- A list can have any number of elements (unlike pairs or tuples)
- All elements in a list have the same type

## Syntax

• A list of values is a value; elements separated by semi-colons:

The empty list is a value:

```
[] (* :: pronounced "nil" *)
```

Prepend an element to beginning of list:

```
e1::e2 (* :: pronounced "cons" *)
```

## Type: <type\_name> list

- [1,2,3]: int list
- [true]: bool list
- [(1,3),(7,8),(9,10)]: int\*int list
- [([0;1],2); ([3;4],2)]: (int list \* int) list
- ∏: 'a list
- Caution: semi-colons in lists, commas in tuples
- Caution: All elements in a list have the same type

## Accessing lists

A list is either:

- nil
- or a head "cons-ed" onto a tail

Use **pattern matching** to access list in one of those ways:

```
let empty lst =
  match lst with
  [] -> true
  | h::t -> false
```

### Example list function 1

```
let rec sum_list (lst:int list) : int =
  match lst with
  [] -> 0
  | h::t -> h + sum_list(t)
```

### Example list function 2

```
let rec length (lst:int list) : int =
  match lst with
  [] -> 0
  | x::xs -> 1 + length(xs)
```

### Example list function 3

```
let rec append ((lst1:'a list),(lst2:'a list))
    : 'a list =
    match lst1 with
    [] -> lst2
    | h::t -> h::append(t,lst2)
(* append is available as built-in operator @ *)
```

### Lists are immutable

- No way to mutate an element of a list
- Instead, build up new lists out of old, e.g., append

What is the type of **31**:: [10]?

A. int

B. int list

C. int\*(int list)

D. (int\*int) list

E. Not well-typed

```
match ["zar";"doz"] with
    [] -> "kitteh"
    | h::t -> h
```

To what value does the above expression evaluate?

- A. "zar"
- B. "doz"
- C. "kitteh"
- D. []
- E. h

- let a = [2;3;4]
- We want to append 5 in the end, what can we do?

 Construct a list that has the integers 1 through 3 in it. Use the square bracket notation for lists.

 Construct the same list, but do not use the square bracket notation. Instead use :: and [].

Construct the same list again, using the @ operator.

 Write a function that returns the product of all the elements in a list. The product of all the elements of an empty list is 1

Write a function that concatenates all the strings in a list.
 The concatenation of all the strings in an empty list is the empty string "".
